ABSTRACT

Background: Laryngeal cancer is the most common of the aerodigestive tract affecting both sexes and all age groups with high morbidity and mortality when left untreated. 

Objectives: The study is carried out to review the histology of all larynx biopsies sent to Histopathology laboratory in UDUTH, Sokoto.

Methods: A total number of forty three (43) paraffin embedded tissue block were used for the study. The blocks were retrieved from the archive and the patients’ bio data and the histopathological pattern from the biopsies record book. The sections were cut from the tissue...
blocks using rotary microtome. They were stained with haematoxylin and eosin staining technique and the photomicrographs, bio data and histopathological pattern were analyzed and the results were presented in tables as percentages.

**Results:** A total of forty three larynx biopsies were received during the period under review, 17 samples (39.5%) were benign lesions while 26 samples (60.5%) were malignant lesions. The age group with the highest occurrences is 0-9 years which were mostly benign with the malignant having the highest age range of 40-49 years. The male to female ratio 5.5: 1 and Squamous cell carcinoma had the highest frequency of 92.3% while non Hodgkins lymphoma and Hybrid carcinozad had the lowest frequency of 3.8% respectively.

**Conclusion:** The study showed that there were more benign larynx lesions occurring during the first decade of life while those in older range (40-49 years) were mostly malignant. We recommend awareness for the early detection of these lesions.

**Keywords:** Larynx biopsies; aerodigestive tract; malignant; juvenile papilloma.

1. INTRODUCTION

Larynx is commonly called the voicebox, is an organ in the neck of amphibians, reptiles, and mammals involved in breathing, sound production, and protecting the trachea against food aspiration and manipulates pitch and volume [1]. The larynx houses the vocal folds (vocal cords), which are essential for phonation. The vocal folds are situated just below where the tract of the pharynx splits into the trachea and the esophagus [1]. Laryngeal cancer is the most common cancer of the aerodigestive tract and it accounts for 20% of all head and neck cancers [2]. The incidence of laryngeal cancer world-wide varies and a number of areas of relative high incidence (>10/100,000) can be identified in Brazil (Sao Paulo), the black populations in parts of the USA, Hong Kong, India (Bombay, Poona), France (Bas Rhins, Doubs), Italy (Varesea), Poland (Katowice), Spain and Switzerland (Geneva) while low incidence areas (<2/100,000) include Japan, Norway, Sweden, New Guinea and Senegal (Dakar) [3]. About 11,300 new cases of laryngeal cancer were diagnosed yearly in United States which account for about 1% of new cancer diagnosed and approximately one third (3,660) of these patients would die of the disease [2,3]. In the United Kingdom the incidence of laryngeal cancer is approximately 4/100,000 (Intermediate to low incidence) with 70% occurring in men (3-4:1) and the peak incidence between 55 and 65 years [4,5]. Globally the male to female sex ratio for laryngeal cancer is accepted to be 10:1 despite regional variations [2]. One characteristic of laryngeal cancer is its greater predominance in men compared with women. In the USA, the male to female ratio is 4:1; in Canada (Mannitoba), 6:1, and in Italy (Varesea) 32:1 where the maximum male to female ratio has been recorded [3]. The etiological factors of laryngeal tumours are cigarette smoking, alcohol, human papiloma virus (strain 16 and 18), gastroesophageal reflux, exposure to toxics inhalation such as asbestos, wood dust, formaldehydes and mustard gas among others [6,7]. There are several disorders of larynx that can prevent it from functioning optimally. These include Laryngitis, Presbylarynx, Ulcers, Polyps and Nodules, Squamous Cell Carcinoma, Verrucous Carcinoma, Vocal Cord Paresis, Idiopathic Laryngeal Spasm, Laryngopharyngeal Reflux. And Laryngomalacia, Laryngeal Perichondritis [8,9,10].

The diagnosis of larynx disorders includes computerized tomography scan (CT-Scan) which include contrast enhanced helical CT scanning, Magnetic resonance imaging (MRI), Positron emission tomography (PET), physical examination, tissue biopsy and Neck x-ray and fluoroscopy [11,12].

2. MATERIALS AND METHODS

2.1 Study Area

This study was carried out in Sokoto State, Nigeria. It is located in the extreme north-western part of Nigeria and it has an estimated population of more than 4.2 million according to 2006 national head count, with an annual average temperature of 38.3°C.

2.2 Type of Study

This is a retrospective analysis of all larynx biopsies carried out between January 2002 to December 2012 in a tertiary health facility of Usmanu Danfodiyo University Teaching Hospital Sokoto, Nigeria.
2.3 Study Population

The study population included 43 tissue blocks of patients with larynx biopsy from January 2002 to December 2012.

2.4 Inclusion and Exclusion Criteria

The inclusion criteria were for patients to have larynx biopsy during the study period. All other patients were excluded from the study.

2.5 Samples Collection and Preparation

Demographic data such as age, sex and site of the biopsy were obtained from the patients' histology request cards and histology registers. The paraffinized embedded blocks were traced, recut and stained using haematoxylin and eosin staining method and reviewed for confirmation.

2.6 Data Analysis

Data obtained was analyzed using EPI INFO VERSION 3.5.4.

3. RESULTS

A total of forty three larynx biopsies were received from January 2002 to December 2012, which amounts to 0.5% of all the biopsies received over that period. Twenty six 26 (60.5%) cases of the larynx biopsies were malignant while benign cases were 17 (39.5%) as shown in Tables 1 and 2. The mean and median ages of 13.4 years and 10 years respectively.

Table 2 and Fig. 8 Show that the sex distribution of the larynx biopsies patients, was 35 (81%) male and 8(19%) female with the male to female ratio of 4:1. Table 3 show that among the various histological types observed in benign lesions, granular cell myoblastoma, inflammatory and laryngeal nodule have the lowest occurrence with 5.9% while juvenile papilloma has the highest occurrence with 58.8%. Whereas in malignant lesions, hybrid carcinoma and non Hodgkin's lymphoma have the lowest occurrence with 3.8% while squamous cell carcinoma has the highest occurrence.

4. DISCUSSION

In this 10 years retrospective study, a total of 43 larynx biopsy samples were received. There were 17 cases (39%) of benign lesions and 26 cases (60.5%) of malignant lesions. This study clearly shows that malignant lesions are most occurrences in our environment. Juvenile papilloma is the most commonly occurring benign tumour, out of 17 cases, 10 cases (58%) were juvenile papilloma. There were 26 cases of malignant lesions and the most common histological type was the Squamous cell carcinoma which constituted 24 cases (92.3%) out of 26 malignant cases. From the age range distribution of patients in Table 1, it is observed that the age groups with the highest frequency were between age range of 0-9 years which account for 20.9% of larynx disorders. Each of this trend is in disagreement with the work of [10] who reported that the peak age range is 50-59years and 30-75 years [11]. This study has showed the involvement of lower age groups from third decade of life in the laryngeal tumour. The reason for this higher involvement of the younger age group in this area and in Nigeria as a whole are not clear but may be attributed to race, genetics, unknown viral infection and nutritional deficiencies in diet and poverty in addition to cigarette smoking and alcohol consumption which are already known strong etiological factors.

Out of the 26 patients with laryngeal carcinoma, 4 (15.4%) were females while 22 (84.6%) were found to be males. Generally, laryngeal carcinoma was observed to be more common among the males than females. Globally, the male to female sex ratio for laryngeal cancer is accepted to be 10:1 despite regional variations [2].

5. CONCLUSION

There were more malignant (60.5%) laryngeal tumours in Sokoto than benign (39.5%) lesions with male preponderance. The prevalent age for malignant lesions was from 35 years to 70 years which signifies a younger population. The study showed that the most common histological types were squamous cell carcinoma and juvenile papilloma.

The findings in this study raise concern on the burden and management challenges of this cancer in our environment. Therefore it is desirable to educate the public about the disease so that early diagnosis and treatment can make a lot of difference in the morbidity and mortality.
6. RECOMMENDATIONS

1. There is need to improve the socio-economic status of the populace, create awareness for subtle signs and symptoms and have high index of suspicion for early diagnosis and appropriate referral.
2. There is need for public enlightenment on the possibility of high cure rates and voice preservation in early laryngeal cancer.
3. Cost of oncology care should be subsidized by government while an oncology centre should be established in each of the six geopolitical zones in Nigeria.
4. Continuous medical education on early detection and investigation of causes of hoarseness will discourage late presentation.
5. Recommend Health policy makers in gap analysis and development of strategic interventions for the control of larynx disorders in the region.
